(54) **Multidimensional systolic array processing apparatus and method.**

(57) A multidimensional systolic array processor uses a multidimensional array of systolically coupled processing elements to perform matrix-vector multiplication of matrix and vector signal sets. A two-dimensional array uses a PxQ matrix (P rows and Q columns) of processing elements which are coupled to systolically process the signals, e.g. via multiplication and accumulation. The processing elements are coupled both row-to-row and column-to-column for pipeline processing within each row and each column, i.e. multidimensional pipelining, thereby increasing processing parallelism and speed. Interconnectivity of the processing elements is minimized by forming separate column and row signal subsets of the vector signal set which are coupled simultaneously to each processing element in the first row and first column, respectively. Size of the processing elements is minimized by reducing local storage of matrix signal subsets within each processing element. Separate column and row signal subsets of the matrix signal set are formed and coupled into each processing element of the first row and first column, respectively. As the matrix column and row signal subsets are systolically processed and transferred row-to-row and column-to-column, respectively, each signal subset is reduced in size by one signal, thereby requiring the transfer and temporary local storage of successively smaller matrix signal subsets. A three-dimensional processor uses a PxQxT array (T planes of P rows and Q columns) of processing elements which are coupled plane-to-plane-to-plane.

EP 0 479 102 A2

FIG. 15

The present invention relates to array processors, and in particular, to systolic array processors which process multiple signals in parallel in multiple dimensions.

Systolic processors, i.e. processors which systolically "pump," or transfer, data from one processing element to another, are well known in the art. Systolic arrays have been used to increase the pipelined computing capability, and therefore the computing speed, of various types of signal processors.

Systolic array processors are particularly useful for processing, e.g. multiplying, two signal sets, where the first signal set represents a matrix parameter set and the second signal set represents a vector parameter set. In other words, the first signal set represents a matrix parameter set which can be represented as an M-by-K ("MxK") matrix having M rows and K columns of parameters, and the second

signal set represents a Kx1 vector having K rows and 1 column of parameters.

Referring to Figure 1, a representation of the matrix-vector multiplication of two such signal sets can be seen. The matrix signal set W has matrix signals $W_{I,J}$ and the vector signal set V has vector signals V_J , where I is an element of the set {1,2,3,...,M} and J is an element of the set {1,2,3,...,K}. This can be expressed mathematically by the following formula:

$$O_I = \sum_{J=1}^K W_{I,J} V_J$$

Such signal sets are also found in many artificial neural network models, including the Hopfield neural network model. Referring to Figure 2, a simple artificial neural network with its associated signal sets can be seen. The first layer of neurons $n_{1,J}$, or nodes, receives some form of input signals I_J , and based thereon, generates a number of voltage signals V_J , which can be represented as a voltage vector V.

Coupling the respective voltage signals V_J to the second layer of neurons $n_{2,I}$ are a number of scaling elements (e.g. "adaptive weights"), which introduce scaling, or "weight," signals $W_{I,J}$ for scaling or "weighting" the voltage signals V_J prior to their being received by the second layer neurons $n_{2,I}$. It will be understood that, with respect to the subscripted notation for representing the scaling or weighting signals $W_{I,J}$, the first subscripted character "I" represents the destination neuron $n_{2,I}$ in the second layer, and the second subscripted character "J" represents the source neuron $n_{1,J}$ of the voltage signal V_J in the first layer.

The simplest form of systolic processing array used for performing the matrix-vector multiplication of signal sets, as discussed above, is one-dimensional. One type of one-dimensional systolic array is a "ring" systolic array, shown in Figure 3. The systolically coupled processing elements N_J are interconnected as shown, with signal flow represented by the arrows. First, the corresponding voltage signals V_J are initially coupled into their corresponding processing elements N_J . Then, following the application of each clock pulse (not shown, but common to each processing element N_J), the matrix signals $W_{I,J}$ are sequentially inputted to their corresponding processing element N_J , as shown. Therein, each matrix signal $W_{I,J}$ is multiplied by its corresponding voltage signal V_J and accumulated, i.e. stored, within the processing element N_J .

Following the next clock signal, the foregoing is repeated, with the voltage signals V_J being transferred to subsequent processing elements N_J to be multiplied by the corresponding matrix signal $W_{I,J}$ therein. For example, the voltage signals V_J which are transferred between the processing elements N_J are shown in parentheses. This is repeated K-1 times, i.e. for a total of K times, to produce the final matrix-vector product outputs O_I . The "ring" configuration facilitates multiple iterations of the matrix-vector products, a desirable feature used in the learning phase of an artificial neural network. Further discussions of the ring systolic array can be found in "Parallel Architectures for Artificial Neural Nets," by S.Y. Kung and J.N. Hwang, IJCNN 1989, pp. II-165 through II-172.

A second type of one-dimensional systolic array relies on a configuration in accordance with the "STAMS" (Systematic Transformation of Algorithms for Multidimensional Systolic arrays) technique. The STAMS technique is discussed in detail in "Algorithms for High Speed Multidimensional Arithmetic and DSP Systolic Arrays," by N. Ling and M.A. Bayoumi, Proceedings of the 1988 International Conference on Parallel Processing, Vol. I, pp. 367-74. An example of a one-dimensional STAMS systolic array is shown in Figure 4.

First, just as in the ring systolic array of Figure 3, the voltage signals V_J are initially inputted into their respective processing elements N_J . Then, the matrix signals $W_{I,J}$ are inputted into the processing elements N_J , with each respective processing element N_J receiving one column of the matrix of matrix signals $W_{I,J}$, as shown. The weight-voltage products are summed with the corresponding weight-voltage products from

the preceding processing element N_{j-1} and then systolically transferred to the next processing element N_{j+1} , and the process continues.

The inputting of the matrix signals $W_{i,j}$ into each successive processing element N_j is delayed by one additional clock pulse per processing element stage to allow for the delays associated with the systolic transferring of the accumulated products. This delay can be accomplished by inputting zeros to a processing element N_j until the systolically transferred accumulated products begin to arrive. However, this delay adversely affects the processing speed. As compared to the ring systolic array of Figure 3 which requires K clock cycles, the STAMS systolic array requires $2K-1$ clock cycles to obtain the product outputs O_i of this matrix-vector multiplication.

A number of problems are associated with using these one-dimensional systolic arrays. One problem involves the inputting of the voltage signals V_j . If the voltages V_j are to be loaded simultaneously in parallel, global interconnects are required to accomplish this. If they are to be loaded sequentially in serial, numerous local interconnects are required, as well as K clock cycles.

Another problem involves the inputting of the matrix signals $W_{i,j}$. If the matrix signals $W_{i,j}$ are stored locally within each processing element N_j , the processing elements N_j must be large enough to provide sufficient storage, i.e. memory, therefor. On the other hand, if the matrix signals $W_{i,j}$ are not stored locally within each processing element N_j , but instead inputted as needed, the global interconnections necessary to do this become complex and impractical. Either many parallel input lines, e.g. a wide signal bus structure, or a large number of clock cycles must be provided.

A third problem involves the amount of time required to perform the matrix-vector multiplication, i.e. $2K-1$ clock cycles for the STAMS systolic array. Although the ring systolic array requires only K clock cycles, the problem remains, as discussed immediately above, of providing either sufficient local matrix signal storage or complex global interconnections.

One approach to addressing these problems of interconnects, storage area and processing time involves the use of multidimensional systolic processing arrays. For example, parallelism, i.e. parallel processing, can be introduced by subdividing the matrix signals $W_{i,j}$ and vector signals V_j . This can be diagrammatically visualized as seen in Figures 5A-5B. This can be expressed mathematically by the following formula:

$$O_i = \sum_{E=0}^{P-1} \sum_{F=0}^{Q-1} W_{i, QE+F+1} V_{QE+F+1}$$

Each row i of the matrix W is divided into P groups of Q signals $W_{i,j}$. In other words, the first of the P groups of Q signals $W_{i,j}$ contains the matrix signals $W_{i,1}-W_{i,Q}$. Similarly, the vector V is divided into P groups of Q voltages V_j . For example, the first of the P groups of Q voltages V_j includes the voltages V_1-V_Q . This can be visualized in even simpler form as shown in Figure 5B.

The processing of these P groups of Q signals $W_{i,j}$, V_j can be accomplished by using several one-dimensional STAMS systolic arrays, such as that shown in Figure 4, in parallel, as shown in Figure 6A. The operation of each separate systolic array is in accordance with that described for the one-dimensional STAMS systolic array of Figure 4 above, with the exception that only Q , rather than K , processing (i.e. clock) cycles are required for each systolic array to complete one subproduct. The subproducts of each array are then summed together to provide the final product outputs O_i . Visualizing this systolic array configuration as two-dimensional is perhaps more easily done by referring to Figure 6B.

This two-dimensional systolic array configuration is an improvement over the one-dimensional STAMS configuration, with respect to processing time. Processing time is reduced since each one-dimensional array, i.e. each pipeline of processors, within the two-dimensional array is shorter and more processing is done in parallel. This configuration requires only $K+Q-1$ clock cycles to obtain the product outputs O_i of the matrix-vector multiplication.

Further improvement has been achieved by extending the two-dimensional STAMS systolic array of Figure 6A to a three-dimensional systolic array. This can be done by further subdividing the matrix W and vector V signals into T groups of P groups of Q signals $W_{i,j}$, V_j . This can be visualized diagrammatically by referring to Figures 7A-7B. This can be expressed mathematically by the following formula:

$$O_i = \sum_{G=0}^{T-1} \sum_{E=0}^{P-1} \sum_{F=0}^{Q-1} W_{i,PG+QE+F+1} V_{PG+QE+F+1}$$

5

As seen in Figure 7A, each row I of the matrix W and the vector V is divided into T groups, which in turn are divided into P groups of Q signals $W_{i,j}$, V_j . For example, the first of the P groups within the first of the T groups contain the matrix signals $W_{1,1}-W_{1,Q}$ and the vector signals V_1-V_Q . Figure 7B represents a more simplified depiction of this multiple subdivision of the matrix W and vector V signals.

Referring to Figure 8A, a realization of such a three-dimensional systolic array is illustrated. Two-dimensional systolic arrays, similar to that illustrated in Figure 6A, are disposed as if on T parallel planes. The operation of each of the T two-dimensional systolic arrays is similar to that as described above for Figure 6A. The subproduct outputs of each of the T two-dimensional arrays are summed together to produce the full product outputs O_i . The three-dimensional nature of this array can perhaps be better visualized by referring to Figure 8B.

This three-dimensional STAMS systolic array configuration is an improvement over the two-dimensional configuration inasmuch as fewer processing, i.e. clock, cycles are required to complete each product output O_i . Processing time is reduced since each one-dimensional array, i.e. each pipeline of processors, within each plane of two-dimensional arrays is shorter and more processing is done in parallel. This three-dimensional configuration requires only $T + K - 1$ clock cycles.

Even though the two-dimensional and three-dimensional STAMS systolic array configurations discussed above provide improvements with respect to processing speed, minimal if any improvement is provided with respect to the number and complexity of the local or global interconnections required for inputting the matrix W and vector V signals. Furthermore, even though the one-dimensional ring systolic array already provides reasonable processing speed, its requisite global interconnections are complex and impractical. Moreover, no improvements are provided by any of the foregoing arrays with respect to matrix signal $W_{i,j}$ storage requirements.

Moreover, the two- and three-dimensional STAMS systolic array configurations described above are not truly two- or three-dimensional, respectively. The two-dimensional array, as well as each two-dimensional array plane within the three-dimensional array, have their processing elements $N_{A,B}$ interconnected along one dimension only, e.g. left to right. Therefore, the systolic processing actually occurs in one dimension only. Thus, full multidimensional parallelism or pipelining is not achieved and maximum processing speed, i.e. minimum processing time, cannot be achieved.

It would be desirable to have a true multidimensional systolic array configuration providing true multidimensional pipeline operation to maximize processing speed. It would be further desirable to have such a multidimensional systolic processing array in which minimal global or local interconnects are required for inputting the matrix and vector signals. It would be still further desirable to have such a multidimensional systolic processing array with minimal matrix signal storage requirements for each processing element.

The present invention addresses these objects and is defined by the independent claims.

A multidimensional systolic array processor in accordance with the present invention has an architecture which maximizes processing parallelism and minimizes global interconnections. Further, the present invention minimizes local matrix signal storage requirements within each processing element.

The present invention maximizes processing parallelism by interconnecting its processing elements along multiple dimensions. Therefore, systolic processing occurs along multiple dimensions. For example, a two-dimensional systolic array processor in accordance with the present invention includes a $P \times Q$ matrix having P rows and Q columns of processing elements, each of which is systolically coupled row-to-row and column-to-column for full pipeline processing within each row and each column. A three-dimensional systolic array processor has a $P \times Q \times T$ array with T planes of P rows and Q columns of processing elements, each of which is systolically coupled plane-to-plane-to-plane for full pipeline processing.

The present invention minimizes global interconnections of the processing elements. For the two-dimensional case, appropriate matrix and vector signal subsets are inputted to only one row and one column of the two-dimensional processing array. These matrix and vector signal subsets are specifically formed so that they need to be inputted to only one row and one column, and yet still be properly processed systolically along all dimensions within the array.

For the three-dimensional case, appropriate matrix and vector signal subsets are inputted to three perpendicular planes of the three-dimensional processing array. For higher-dimensional cases, appropriate matrix and vector signal subsets are similarly inputted to the higher-dimensional processing arrays.

The present invention minimizes local matrix signal storage requirements by inputting specifically formed matrix signal subsets to only one row and one column of the two-dimensional processing array, and to three perpendicular planes of the three-dimensional processing array. These matrix signal subsets are formed to allow the sizes of the matrix signal subsets to be reduced as they are systolically transferred to subsequent processing elements along each dimension within the array. As the matrix signal subsets decrease in size through the array, the local storage, e.g. memory, needed for temporarily storing each matrix signal subset within each processing element is successively reduced. Processing speed is not sacrificed since the matrix signal subsets are transferred to the subsequent processing element at a clock rate higher than that used for systolically transferring the vector signal subsets.

These and other objectives, features and advantages of the present invention will be understood upon consideration of the following detailed description of the invention and the accompanying drawings.

Figure 17 further illustrates the reduced local matrix signal storage requirements of the two-dimensional processor of Figure 13.

Figure 18 illustrates a block diagram of a three-dimensional systolic array processor in accordance with the present invention.

Referring to Figure 9, the Layer 1 and 2 neurons n_1 , n_2 of an artificial neural network (as shown in Figure 1) are reconfigured into two-dimensional neural arrays. The original input signals I_j now have double subscripted notation to reflect the two-dimensional set of input signals $I_{Y,Z}$. Similarly, the original voltage signals V_j now have double subscripted notation to reflect the two-dimensionality of the set of voltage signals $V_{Y,Z}$. Indicated in brackets for some of the Layer 1 neurons in Figure 9 are the original Layer 1 neuron and voltage identifiers (the remaining identifiers being left out for clarity).

The Layer 2 neurons also now have double subscripted notation to reflect the new two-dimensionality of the set of Layer 2 neurons $n_{A,B}$. Indicated in brackets for some of the Layer 2 neurons are the original Layer 2 neuron identifiers (the remaining identifiers being left out for clarity).

The original matrix, e.g. "weight," signals $W_{i,j}$ now have quadruple subscripted notation to reflect their new multidimensionality, i.e. $W_{A,B,Y,Z}$. The first subscripted pair of characters "A,B" represents the destination neuron $n_{A,B}$ in the second layer. The second subscripted pair of characters "Y,Z" represents the source of the voltage signal $V_{Y,Z}$ in the first layer. Indicated in brackets for some of the matrix signals $W_{A,B,Y,Z}$ are the original matrix signal identifiers $W_{i,j}$ (the remaining identifiers being left out for clarity).

It should be understood that the representations of the Layer 1 and 2 neurons, along with their subscripted notations, were selected arbitrarily. They can be reconfigured as desired, provided that the resulting subscripted notation for the matrix signals be consistent therewith.

It should be further understood that it has been assumed for the sake of simplicity that $M=K$ for the

reconfigured array of Layer 2 neurons as represented in Figure 9. However, this is not necessary to the present invention. Ideally, the numbers of rows and columns should be equal, i.e. $P=Q$. This is to maximize the improvements in processing speed and to minimize the local matrix signal storage requirements in accordance with the present invention. However, if K cannot be expressed as a square, i.e. if $P \neq Q$, then the numbers of neurons in both Layers 1 and 2 can be approximated to the nearest square. Extra processing cycles would be required because of such an approximation, but significant improvements in processing speed and local matrix signal storage requirements would still be realized.

Referring to Figure 10, the reconfiguration of the one-dimensional vector signal set V_J of Figure 1 into a two-dimensional vector signal set $V_{Y,Z}$ can be understood. The one-dimensional vector signal set V_J is initially mapped into a two-dimensional vector signal set with the original subscripted notation left intact. This two-dimensional vector signal set is then given new double subscripted notation to reflect the two-dimensionality of the reconfigured vector signal set $V_{Y,Z}$.

Also indicated in Figure 10 (with dashed lines within the two-dimensional vector signal sets) are two vector signal subsets. One is referred to as the vector column signal subset V_C and the other is referred to as the vector row signal subset V_R . These vector signal subsets V_C , V_R are multiplied by the matrix signals $W_{A,B,Y,Z}$, as represented in Figure 9. The matrix signals $W_{A,B,Y,Z}$ are separated into corresponding matrix column W_C and row W_R signal subsets. The vector column V_C and row V_R signal subsets are multiplied by the matrix column W_C and row W_R signal subsets, respectively, as shown in Figures 11 and 12. Therefore, the matrix-vector products O_i are identified according to the following formulas:

$$O_1 = O_C + O_R$$

where:

$$O_C = \sum_{Z=1}^Q \sum_{Y=X}^P W_{A,B,Y,Z} V_J$$

$$J = Y - Z - P + \sum_{Z=1}^Z (P - Z + 2)$$

$$X = \begin{cases} Z, & \text{for odd } Z \\ Z + 1, & \text{for even } Z; \end{cases}$$

and

$$O_R = \sum_{Y=1}^P \sum_{Z=X}^Q W_{A,B,Y,Z} V_J$$

$$J = Z - Y - Q + \sum_{Y=1}^Y (Q - Y + 2)$$

$$X = \begin{cases} Y, & \text{for even } Y \\ Y + 1, & \text{for odd } Y. \end{cases}$$

Based upon the foregoing, the vector V_C , V_R and matrix W_C , W_R signal subsets can be identified according to the following formulas:

$$V_C = V_{Y,Z} = V_J$$

$$W_C = W_{A,B,Y,Z}$$

where:

$$J = Y - Z - P + \sum_{Z=1}^Z (P - Z + 2)$$

5

$Z = 1, 2, 3, \dots, Q$
 $Y = X, X+1, X+2, \dots, P$
 $X = Z, \text{ for odd } Z$
 $= Z+1, \text{ for even } Z;$

10 and

$$V_R = V_{Y,Z} = V_J$$

$$W_R = W_{A,B,Y,Z}$$

15

where:

$$J = Z - Y - Q + \sum_{Y=1}^Y (Q - Y + 2)$$

20

$Y = 1, 2, 3, \dots, P$
 $Z = X, X+1, X+2, \dots, Q$
 $X = Y, \text{ for even } Y$
 $= Y+1, \text{ for odd } Y.$

25

Referring to Figure 13, a two-dimensional systolic processing array 100 in accordance with the present invention includes K processing elements 102, designated by $N_{A,B}$ where A is an element of the set $\{1, 2, 3, \dots, P\}$, B is an element of the set $\{1, 2, 3, \dots, Q\}$ and $K = PQ$. The processing elements 102 are interconnected in a two-dimensional matrix 100 having P rows and Q columns.

30

The processing elements 102 are mutually coupled column-to-column via matrix row subset signal lines 104 and vector row subset signal lines 106. These signal lines 104, 106 provide the means by which the matrix W_R and vector V_R row signal subsets are systolically transferred column-to-column among the processing elements 102. The processing elements 102 are further mutually coupled row-to-row via matrix column subset signal lines 108 and vector column subset signal lines 110. It is by these signal lines 108, 110 that the matrix W_C and vector V_C signal subsets are systolically transferred row-to-row among the processing elements 102.

35

All processing elements 102 in the first row 112 receive a vector signal input 114 which is a vector column signal subset V_C of the vector signal set V. All processing elements 102 in the first row 112 further receive a matrix signal input 116 which is a matrix column signal subset W_C of the matrix signal set W.

40

All processing elements 102 in the first column 118 receive a vector signal input 120 which is a vector row signal subset V_R of the vector signal set V. All processing elements 102 in the first column 118 further receive a matrix signal input 122 which is a matrix row signal subset W_R of the matrix signal set W.

45

All processing elements 102 within the matrix 100 further receive two clock signals. The first clock signal, a multiply-accumulate ("MAC") clock 124, initiates and provides the timing for the multiply-accumulate operation (discussed more fully below) within each processing element 102. The second clock signal, a weight transfer ("WT") clock 126, initiates and provides the timing for the transfer of the matrix, e.g. weight, signals $W_{i,j}$ among the processing elements 102 (discussed more fully below).

50

The vector column signal subset V_C is inputted in parallel to all processing elements 102 within the first row 112, one signal at a time in accordance with the MAC clock 124. As each signal of this signal subset V_C is inputted, the corresponding signals in the matrix column signal subset W_C (according to the formula given above) are also inputted to the processing elements 102 within the first row 112. The number of signals from the matrix column signal subset W_C which are inputted with each signal of the vector column signal subset V_C is P, one for each of the processing elements 102 in each column (discussed more fully below).

55

Similarly, the vector row signal subset V_R is inputted in parallel to all processing elements 102 in the first column 118, one signal at a time in accordance with the MAC clock 124. Inputted in parallel therewith are the corresponding signals from the matrix row signal subset W_R (according to the formula given above). The number of these corresponding signals within the matrix row signal subset W_R is Q, one for each

processing element 102 within each row (discussed more fully below).

As discussed further below, the matrix W_C and vector V_C column signal subsets and matrix W_R and vector V_R row signal subsets are multiplied simultaneously and then added in each processing element 102. After completing the matrix-vector subproducts and accumulation thereof for the first column and row signals of the column W_C , V_C and row W_R , V_R signal subsets, this process is repeated for the second column and row signals. However, as discussed further below, the matrix column W_C and row W_R signal subsets each contain fewer signals following each multiplication and accumulation.

The number of signals to be transferred within each matrix column W_C or row W_R signal subset is greater than the corresponding signal in the vector column V_C or row V_R signal subset, respectively. Therefore, the row-to-row or column-to-column transferring of the matrix column W_C and row W_R signal subsets should be done at a higher rate than the corresponding transfer of the vector column V_C and row V_R signal subsets, respectively. Thus, the WT clock 126 operates at a higher frequency than the MAC clock 124.

The rate of the WT clock 126 is the greater of either P- or Q- times that of the MAC clock 124. It will be understood that this provides for transferring all corresponding matrix signals W_C , W_R (P signals from the matrix column signal subset W_C , and Q signals from the matrix row signal subset W_R) "simultaneously" with their corresponding vector signal subsets V_C , V_R . Processing speed is not sacrificed for this, since the multiply-accumulate operation performed on each vector signal subset V_C , V_R requires more time than the mere transfer of one matrix signal $W_{i,j}$ to the next processing element 102.

Referring to Figure 14, a single processing element $N_{A,B}$ representative of all processing elements 102 within the matrix 100 is illustrated. As discussed above, input signals 104a, 106a, 108a, 110a include the matrix W_R and vector V_R row signal subsets, and matrix W_C and vector V_C column signal subsets which are systolically transferred from prior processing elements 102 in the preceding column and row, respectively. Further input signals, as discussed above, include the MAC clock 124 and WT clock 126.

Output signals 104b, 106b, 108b, 110b include the matrix W_R and vector V_R row signal subsets, and the matrix W_C and vector V_C column signal subsets which are systolically transferred to subsequent processing elements 102 in the next column and row, respectively. As discussed more fully below, the output matrix W_R , W_C signal subsets 104b, 108b contain fewer members, i.e. signals, than their corresponding input matrix W_R , W_C signal subsets 104a, 108a. Another output signal 128 is the matrix-vector subproduct signal O_i .

The two-dimensional operation of the systolic processing array 100 in accordance with the present invention, as shown in Figure 9, is substantially faster. It can be shown that the total processing, e.g. computation, time is $P(P+1)/2 - (P/2) + P$ cycles (i.e. of MAC clock 124). This is substantially faster than the quasi two-dimensional array of Figure 6A discussed above. Mathematically, the improvement in processing speed can be expressed by the following formula:

$$\frac{[P(P+1)/2 - (P/2) + P]}{Q+K-1}$$

For example, if $P=Q=10$ (and therefore $K=100$), the quasi two-dimensional array of Figure 6A requires $Q+K-1=10+100-1=109$ cycles. The array 100 of the present invention, however, only requires $10(10+1)/2 - (10/2) + 10 = 60$ cycles. As the array 100 size increases, i.e. as P and Q become greater, the improvement in processing speed of the present invention is enhanced further. It can be shown that this improvement becomes enhanced by as much as 50% over that of the quasi two-dimensional array of Figure 6A.

Referring to Figure 15, the operation, e.g. multiply-accumulate (MAC) function, of each processing element 102 can be understood. The matrix W_R , W_C signal subsets are inputted and stored in matrix storage elements 204, 208 (e.g. memory circuits or registers). The corresponding vector V_R , V_C signal subsets are inputted and selectively stored in vector signal storage elements 206, 210 (e.g. memory circuits or registers). The corresponding matrix W_C and vector V_C column signals are then multiplied, as are the corresponding matrix W_R and vector V_R row signals in multipliers 212, 214. It should be understood that the vector V_R , V_C signal subsets need not necessarily be stored, but instead can be inputted directly into their respective multipliers 212, 214.

The resulting matrix-vector subproducts are then summed together in an adder 216. It will be recognized that this multiplication and summation can be done with digital multipliers and adders, or alternatively, a microprocessor can be programmed to perform this. The remaining matrix W_R , W_C and vector V_R , V_C signal subsets are then systolically transferred to subsequent processing elements 102.

Referring to Figure 16, the systolic transferring and local storage of successively smaller groups of

signals from the matrix column signal subset W_C can be understood. As discussed above, the matrix column signal subset W_C initially has P members, i.e. signals, for each corresponding signal from the vector column signal subset V_C . These corresponding matrix W_C and vector V_C signal subsets are then transferred to the second processing element $N_{2,1}$ in the first column 118 via the matrix 108 and vector 110 column subset signal lines.

However, as discussed above for Figure 11, the first of the signals within the matrix column signal subset W_C corresponding to the inputted signal from the vector column signal subset V_C has already been processed and is no longer needed. Therefore it need not be transferred, i.e. only $P-1$ signals of the matrix column signal subset W_C need to be transferred to the second processing element $N_{2,1}$. Therefore, whereas the storage registers, e.g. memory, within the first processing element $N_{1,1}$ must be large enough to store P matrix signals, the corresponding registers within the second processing element $N_{2,1}$ need only be large enough to store $P-1$ matrix signals.

Similarly, the third processing element $N_{3,1}$ need only store $P-2$ matrix signals, and so on. This continues until the last processing element $N_{P,1}$ which need only contain enough storage area to store one matrix signal. Thus, it can be seen that local storage requirements for the matrix column signal subsets W_C for all processing elements 102 within the first column 118 total $P(P+1)/2$ storage registers. Since each of the Q columns of processing elements 102 are identical, total storage requirements for the full array 100 for the matrix column signal subsets W_C are $QP(P+1)/2$ storage registers.

Referring to Figure 17, the reduced local storage requirements for the matrix row signal subsets W_R can similarly be understood. As discussed above, corresponding signals from the vector V_R and matrix W_R row signal subsets are inputted into each processing element 102 in the first row 112 of the array 100. As the vector row signal subset V_R is systolically processed and transferred column-to-column through the array 100, its corresponding matrix row signal subset W_R is transferred therewith.

However, as discussed above, the number of corresponding signals within the transferred matrix row signal subset W_R is reduced by one signal with each systolic processing cycle and transfer. For example, the first processing element $N_{1,1}$ in the first row 112 of processing elements 102 receives a signal from the vector row signal subset V_R , and a corresponding group of signals from the corresponding matrix row signal subset W_R , which has Q members, i.e. signals. After processing by the first processing element $N_{1,1}$, the first matrix signal within the matrix row signal subset W_R is no longer needed, and therefore need not be transferred to the second processing element $N_{1,2}$. Thus, only $Q-1$ signals of the matrix row signal subset W_R are transferred and stored within the second processing element $N_{1,2}$.

This continues to be true as the vector V_R and matrix W_R row signal subsets are systolically processed and transferred column-to-column through the array 100. Thus, the last processing element $N_{1,Q}$ need provide local storage registers for only one signal from the matrix row signal subset W_R .

Based upon the foregoing, it can be shown that the total local storage requirements for all processing elements 102 within each row are $Q(Q+1)/2$ storage registers. Including all P rows of processing elements 102, the total local storage requirements for storing the matrix row signal subsets W_R are $PQ(Q+1)/2$ storage registers.

Therefore, it can be shown that for the case of $P=Q$ and $K=PQ$, the total local storage requirements for both the matrix column W_C and row W_R signal subsets are $P^2(P+1)$ storage registers. This represents a significant improvement over the local storage requirements of the quasi two-dimensional array of Figure 6A. For example, for the case of $P=Q$ and $K=PQ$, local matrix signal storage requirements are reduced approximately by a factor of P , or more precisely, according to the following formula:

$$\frac{PQ(P+1)}{(PQ)(PQ)} = P^2(P+1)/P^4 = (P+1)/P^2$$

It should be understood that the foregoing principles of a two-dimensional systolic array in accordance with the present invention can also be extended to a three-dimensional systolic array. In such a three-dimensional systolic array, all adjacent processing elements along all three dimensions are mutually coupled for systolically processing and transferring the matrix and vector signal subsets. Whereas the quasi three-dimensional systolic array of Figure 8A requires $T+K-1$ processing cycles to produce the product outputs O_i , a fully three-dimensional systolic array in accordance with the present invention requires only approximately $P(P+1)(2P+1)/12$ processing cycles (for $P=Q=T$).

Referring to Figure 18, a block diagram of a three-dimensional systolic processing array in accordance with the present invention for $P=Q=T=3$ is illustrated. Pipelining is done in all three dimensions simultaneously as shown. The matrix W_{P1} , W_{P2} , W_{P3} and vector V_{P1} , V_{P2} , V_{P3} signal subsets are inputted to

three perpendicular planes of processing elements. As in the two-dimensional case discussed above, the corresponding matrix and vector signals are inputted into their respective processing elements sequentially, multiplied and accumulated therein. The remaining corresponding matrix and vector signals are then systolically transferred to subsequent processing elements plane-by-plane-by-plane throughout the three-dimensional processing array.

It will be recognized that the "cube" to which the corresponding matrix and vector signals are transferred becomes smaller by one processing element on all sides. For example, starting at a corner processing element $N_{1,1,1}$, the matrix W_{P1} , W_{P2} , W_{P3} and vector V_{P1} , V_{P2} , V_{P3} signal subsets are initially inputted to three perpendicular planes of processing elements. The matrix and vector signals are then systolically transferred to subsequent processing elements plane-by-plane-by-plane throughout the three-dimensional processing array, with a new "corner" processing element $N_{2,2,2}$ located one processing element in from the initial corner processing element $N_{1,1,1}$.

Hence, it can be seen from the foregoing that a multidimensional systolic array processor in accordance with the present invention provides improved processing speed due to the full multidimensionality of its processing element interconnections, improved global interconnectivity (e.g. by requiring external connections to only one row and one column of the two-dimensional array), and reduced local storage requirements by avoiding the unnecessary transferring and local storage of unneeded matrix signals.

It should be understood that various alternatives to the embodiments of the present invention described herein can be employed in practicing the present invention. It is intended that the following claims define the scope of the present invention, and that structures and methods within the scope of these claims and their equivalents be covered thereby.

Claims

1. A multidimensional systolic array processor comprising:
a signal processing array systolically coupled in a $P \times Q$ matrix having P rows and Q columns of processing means $N_{A,B}$, where $A \in \{1,2,3,\dots,P\}$ and $B \in \{1,2,3,\dots,Q\}$, to systolically process a matrix signal set W having matrix signals $W_{I,J}$ and a vector signal set V having vector signals V_J , where $I \in \{1,2,3,\dots,M\}$ and $J \in \{1,2,3,\dots,K\}$, said matrix signal set W representing a matrix parameter set selectively represented as an $M \times K$ matrix having M rows and K columns of parameters, and said vector signal set V representing a vector parameter set selectively represented as a K -element vector having K parameters, wherein each processing means $N_{I,B}$ in a first one of said rows of processing means $N_{A,B}$ is coupled to receive a vector column signal subset V_C of said vector signal set V , where

$$V_C = V_{Y,Z} = V_J$$

where:

$$J = Y - Z - P + \sum_{Z=1}^Z (P - Z + 2)$$

$$\begin{aligned} Z &= 1, 2, 3, \dots, Q \\ Y &= X, X+1, X+2, \dots, P \\ X &= Z, \text{ for odd } Z \\ &= Z+1, \text{ for even } Z. \end{aligned}$$

2. An array processor as recited in Claim 1, wherein each processing means $N_{A,1}$ in a first one of said columns of processing means $N_{A,B}$ is coupled to receive a vector row signal subset V_R of said vector signal set V , where

$$V_R = V_{Y,Z} = V_J$$

where:

$$J = Z - Y - Q + \sum_{Y=1}^Y (Q - Y + 2)$$

5

$$\begin{aligned} Y &= 1, 2, 3, \dots, P \\ Z &= X, X+1, X+2, \dots, Q \\ X &= Y, \text{ for even } Y \\ &= Y+1, \text{ for odd } Y. \end{aligned}$$

10

3. An array processor as recited in Claim 1, wherein said systolic coupling of said processing means $N_{A,B}$ comprises individually coupling each processing means $N_{A,B}$ in each row with a corresponding processing means $N_{A-1,B}$ in a preceding row via a vector column subset signal line $L_{VC(A-1)}$ and a matrix column subset signal line $L_{WC(A-1)}$, and individually coupling each processing means $N_{A,B}$ in each row with a corresponding processing means $N_{A+1,B}$ in a subsequent row via a vector column subset signal line $L_{VC(A+1)}$ and a matrix column subset signal line $L_{WC(A+1)}$.

15

4. An array processor as recited in Claim 2, wherein said systolic coupling of said processing means $N_{A,B}$ comprises individually coupling each processing means $N_{A,B}$ in each column with a corresponding processing means $N_{A,B-1}$ in a preceding column via a vector row subset signal line $L_{VR(B-1)}$ and a matrix row subset signal line $L_{WR(B-1)}$, and individually coupling each processing means $N_{A,B}$ in each column with a corresponding processing means $N_{A,B+1}$ in a subsequent column via a vector row subset signal line $L_{VR(B+1)}$ and a matrix row subset signal line $L_{WR(B+1)}$.

20

5. A multidimensional systolic array processor comprising:

25

a signal processing array systolically coupled in a $P \times Q$ matrix having P rows and Q columns of processing means $N_{A,B}$, where $A \in \{1, 2, 3, \dots, P\}$ and $B \in \{1, 2, 3, \dots, Q\}$, to systolically process a matrix signal set W having matrix signals $W_{I,J}$ and a vector signal set V having vector signals V_J , where $I \in \{1, 2, 3, \dots, M\}$ and $J \in \{1, 2, 3, \dots, K\}$, said matrix signal set W representing a matrix parameter set selectively represented as an $M \times K$ matrix having M rows and K columns of parameters, and said vector signal set V representing a vector parameter set selectively represented as a K -element vector having X parameters, wherein each processing means $N_{1,B}$ in a first one of said rows of processing means $N_{A,B}$ is coupled to receive a matrix column signal subset W_C of said matrix signal set W , where

30

$$W_C = W_{A,B,Y,Z}$$

35

where:

40

$$J = Y - Z - P + \sum_{Z=1}^Z (P - Z + 2)$$

$$\begin{aligned} Z &= 1, 2, 3, \dots, Q \\ Y &= X, X+1, X+2, \dots, P \\ X &= Z, \text{ for odd } Z \\ &= Z+1, \text{ for even } Z, \end{aligned}$$

45

and further wherein said matrix column signal subset W_C is systolically coupled row-to-row within said matrix of processing means $N_{A,B}$, said coupled matrix column signal subset W_C having fewer signals when coupled from one of said rows of processing means $N_{A,B}$ to a subsequent row of processing means $N_{A+1,B}$.

50

6. An array processor as recited in Claim 5, wherein each processing means $N_{A,1}$ in a first one of said columns of processing means $N_{A,B}$ is coupled to receive a matrix row signal subset W_R of said matrix signal set W , where

55

$$W_R = W_{A,B,Y,Z}$$

where:

$$J = Z - Y - Q + \sum_{Y=1}^Y (Q - Y + 2)$$

5

$$\begin{aligned} Y &= 1, 2, 3, \dots, P \\ Z &= X, X+1, X+2, \dots, Q \\ X &= Y, \text{ for even } Y \\ &= Y+1, \text{ for odd } Y, \end{aligned}$$

10 and further wherein said matrix row signal subset W_R is systolically coupled column-to-column within said matrix of processing means $N_{A,B}$, said coupled matrix row signal subset W_R having fewer signals when coupled from one of said columns of processing means $N_{A,B}$ to a subsequent column of processing means $N_{A,B+1}$.

15 7. An array processor as recited in Claim 5; wherein said systolic coupling of said processing means $N_{A,B}$ comprises individually coupling each processing means $N_{A,B}$ in each row with a corresponding processing means $N_{A-1,B}$ in a preceding row via a vector column subset signal line $L_{VC(A-1)}$ and a matrix column subset signal line $L_{WC(A-1)}$, and individually coupling each processing means $N_{A,B}$ in each row with a corresponding processing means $N_{A+1,B}$ in a subsequent row via a vector column subset signal line $L_{VC(A+1)}$ and a matrix column subset signal line $L_{WC(A+1)}$.

20 8. An array processor as recited in Claim 6, wherein said systolic coupling of said processing means $N_{A,B}$ comprises individually coupling each processing means $N_{A,B}$ in each column with a corresponding processing means $N_{A,B-1}$ in a preceding column via a vector row subset signal line $L_{VR(B-1)}$ and a matrix row subset signal line $L_{WR(B-1)}$, and individually coupling each processing means $N_{A,B}$ in each column with a corresponding processing means $N_{A,B+1}$ in a subsequent column via a vector row subset signal line $L_{VR(B+1)}$ and a matrix row subset signal line $L_{WR(B+1)}$.

25 9. A multidimensional systolic array processor comprising:
30 a signal processing array systolically coupled in a $P \times Q$ matrix having P rows and Q columns of processing means $N_{A,B}$, where $A \in \{1, 2, 3, \dots, P\}$ and $B \in \{1, 2, 3, \dots, Q\}$, to systolically process a matrix signal set W having matrix signals $W_{i,j}$ and a vector signal set V having vector signals V_j , where $i \in \{1, 2, 3, \dots, M\}$ and $j \in \{1, 2, 3, \dots, K\}$, said matrix signal set W representing a matrix parameter set selectively represented as an $M \times K$ matrix having M rows and K columns of parameters, and said vector signal set V representing a vector parameter set selectively represented as a K -element vector having K parameters, wherein each processing means $N_{i,B}$ in a first one of said rows of processing means $N_{A,B}$ is coupled to receive a vector column signal subset V_C of said vector signal set V , where

$$V_C = V_{Y,Z} = V_j$$

40

where:

45

$$J = Y - Z - P + \sum_{Z=1}^Z (P - Z + 2)$$

$$\begin{aligned} Z &= 1, 2, 3, \dots, Q \\ Y &= X, X+1, X+2, \dots, P \\ 50 \quad X &= Z, \text{ for odd } Z \\ &= Z+1, \text{ for even } Z, \end{aligned}$$

and further wherein each processing means $N_{i,B}$ in a first one of said rows of processing means $N_{A,B}$ is coupled to receive a matrix column signal subset W_C of said matrix signal set W , where

$$55 \quad W_C = W_{A,B;Y,Z}$$

where:

$$J = Y - Z - P + \sum_{Z=1}^Z (P - Z + 2)$$

5

$$\begin{aligned} Z &= 1, 2, 3, \dots, Q \\ Y &= X, X+1, X+2, \dots, P \\ X &= Z, \text{ for odd } Z \\ &= Z+1, \text{ for even } Z, \end{aligned}$$

- 10 and still further wherein said matrix column signal subset W_C is systolically coupled row-to-row within said matrix of processing means $N_{A,B}$, said coupled matrix column signal subset W_C having fewer signals when coupled from one of said rows of processing means $N_{A,B}$ to a subsequent row of processing means $N_{A+1,B}$.

- 15 10. An array processor as recited in Claim 9, wherein each processing means $N_{A,1}$ in a first one of said columns of processing means $N_{A,B}$ is coupled to receive a vector row signal subset V_R of said vector signal set V , where

$$V_R = V_{Y,Z} = V_J$$

20

where:

$$J = Z - Y - Q + \sum_{Y=1}^Y (Q - Y + 2)$$

25

$$\begin{aligned} Y &= 1, 2, 3, \dots, P \\ Z &= X, X+1, X+2, \dots, Q \\ X &= Y, \text{ for even } Y \\ &= Y+1, \text{ for odd } Y. \end{aligned}$$

30

11. An array processor as recited in Claim 10, wherein each processing means $N_{A,1}$ in a first one of said columns of processing means $N_{A,B}$ is coupled to receive a matrix row signal subset W_R of said matrix signal set W , where

35

$$W_R = W_{A,B;Y,Z}$$

where:

40

$$J = Z - Y - Q + \sum_{Y=1}^Y (Q - Y + 2)$$

45

$$\begin{aligned} Y &= 1, 2, 3, \dots, P \\ Z &= X, X+1, X+2, \dots, Q \\ X &= Y, \text{ for even } Y \\ &= Y+1, \text{ for odd } Y, \end{aligned}$$

50

and further wherein said matrix row signal subset W_R is systolically coupled column-to-column within said matrix of processing means $N_{A,B}$, said coupled matrix row signal subset W_R having fewer signals when coupled from one of said columns of processing means $N_{A,B}$ to a subsequent column of processing means $N_{A,B+1}$.

- 55 12. An array processor as recited in Claim 9, wherein said systolic coupling of said processing means $N_{A,B}$ comprises individually coupling each processing means $N_{A,B}$ in each row with a corresponding processing means $N_{A-1,B}$ in a preceding row via a vector column subset signal line $L_{VC(A-1)}$ and a matrix column subset signal line $L_{WC(A-1)}$, and individually coupling each processing means $N_{A,B}$ in each row

with a corresponding processing means $N_{A+1,B}$ in a subsequent row via a vector column subset signal line $L_{VC(A+1)}$ and a matrix column subset signal line $L_{WC(A+1)}$.

13. An array processor as recited in Claim 10, wherein said systolic coupling of said processing means $N_{A,B}$ comprises individually coupling each processing means $N_{A,B}$ in each column with a corresponding processing means $N_{A,B-1}$ in a preceding column via a vector row subset signal line $L_{VR(B-1)}$ and a matrix row subset signal line $L_{WR(B-1)}$, and individually coupling each processing means $N_{A,B}$ in each column with a corresponding processing means $N_{A,B+1}$ in a subsequent column via a vector row subset signal line $L_{VR(B+1)}$ and a matrix row subset signal line $L_{WR(B+1)}$.
14. An array processor as recited in Claim 1 or 9, wherein each one of said processing means $N_{1,B}$ in said first row of processing means $N_{A,B}$ is coupled to receive said vector column signal subset V_C substantially simultaneously.
15. An array processor as recited in Claim 2 or 10, wherein each one of said processing means $N_{A,1}$ in said first column of processing means $N_{A,B}$ is coupled to receive said vector row signal subset V_R substantially simultaneously.
16. An array processor as recited in Claim 5 or 9, wherein each one of said processing means $N_{1,B}$ in said first row of processing means $N_{A,B}$ is coupled to receive said matrix column signal subset W_C substantially simultaneously.
17. An array processor as recited in Claim 6 or 10, wherein each one of said processing means $N_{A,1}$ in said first column of processing means $N_{A,B}$ is coupled to receive said matrix row signal subset W_R substantially simultaneously.
18. An array processor as recited in Claim 1 or 5 or 9, wherein each one of said processing means $N_{A,B}$ comprises a multiplier-accumulator.
19. An array processor as recited in Claim 18, wherein said multiplier-accumulator comprises a digital adder and a digital register.
20. An array processor as recited in Claim 1 or 5 or 9, wherein each one of said processing means $N_{A,B}$ comprises a plurality of digital registers.
21. A method of systolically processing a plurality of signal sets, comprising the steps of:
 - (a) providing a signal processing array systolically coupled in a $P \times Q$ matrix having P rows and Q columns of processing means $N_{A,B}$, where $A \in \{1,2,3,\dots,P\}$ and $B \in \{1,2,3,\dots,Q\}$;
 - (b) coupling into said processing array a matrix signal set W having matrix signals $W_{i,j}$ representing a matrix parameter set selectively represented as an $M \times K$ matrix having M rows and K columns of parameters, where $i \in \{1,2,3,\dots,M\}$ and $j \in \{1,2,3,\dots,K\}$;
 - (c) coupling into said processing array a vector signal set V having vector signals V_j representing a vector parameter set selectively represented as a K -element vector having K parameters, wherein a vector column signal subset V_C of said vector signal set V is coupled into each processing means $N_{1,B}$ in a first one of said rows of processing means $N_{A,B}$, where

$$V_C = V_{1,Z} = V_j$$

where:

$$J = Y - Z - P + \sum_{Z=1}^Z (P - Z + 2)$$

$$\begin{aligned} Z &= 1, 2, 3, \dots, Q \\ Y &= X, X+1, X+2, \dots, P \\ X &= Z, \text{ for odd } Z \end{aligned}$$

= Z + 1, for even Z; and
(d) systolically processing said matrix W and vector V signal sets.

22. A method of systolically processing a plurality of signal sets, comprising the steps of:

- 5 (a) providing a signal processing array systolically coupled in a PxQ matrix having P rows and Q columns of processing means $N_{A,B}$, where $A \in \{1,2,3,\dots,P\}$ and $B \in \{1,2,3,\dots,Q\}$;
(b) coupling into said processing array a matrix signal set W having matrix signals $W_{i,j}$ representing a matrix parameter set selectively represented as an MxK matrix having M rows and K columns of parameters, where $i \in \{1,2,3,\dots,M\}$ and $j \in \{1,2,3,\dots,K\}$, wherein a matrix column signal subset W_C of said matrix signal set W is coupled into each processing means $N_{1,B}$ in a first one of said rows of
10 processing means $N_{A,B}$, where

$$W_C = W_{A,B,Y,Z}$$

15 where:

$$J = Y - Z - P + \sum_{Z=1}^Z (P - Z + 2)$$

20

$$\begin{aligned} Z &= 1, 2, 3, \dots, Q \\ Y &= X, X+1, X+2, \dots, P \\ X &= Z, \text{ for odd } Z \\ &= Z+1, \text{ for even } Z, \end{aligned}$$

25

and further wherein said matrix column signal subset W_C is systolically coupled row-to-row within said matrix of processing means $N_{A,B}$, said coupled matrix column signal subset W_C having fewer signals when coupled from one of said rows of processing means $N_{A,B}$ to a subsequent row of processing means $N_{A+1,B}$;

- 30 (c) coupling into said processing array a vector signal set V having vector signals V_j representing a vector parameter set selectively represented as a K-element vector having K parameters; and
(d) systolically processing said matrix W and vector V signal sets.

23. A method of systolically processing a plurality of signal sets, comprising the steps of:

- 35 (a) providing a signal processing array systolically coupled in a PxQ matrix having P rows and Q columns of processing means $N_{A,B}$, where $A \in \{1,2,3,\dots,P\}$ and $B \in \{1,2,3,\dots,Q\}$;
(b) coupling into said processing array a matrix signal set W having matrix signals $W_{i,j}$ representing a matrix parameter set selectively represented as an MxK matrix having M rows and K columns of parameters, where $i \in \{1,2,3,\dots,M\}$ and $j \in \{1,2,3,\dots,K\}$, wherein a matrix column signal subset W_C of said matrix signal set W is coupled into each processing means $N_{1,B}$ in a first one of said rows of
40 processing means $N_{A,B}$, where

$$W_C = W_{A,B,Y,Z}$$

45 where:

$$J = Y - Z - P + \sum_{Z=1}^Z (P - Z + 2)$$

50

$$\begin{aligned} Z &= 1, 2, 3, \dots, Q \\ Y &= X, X+1, X+2, \dots, P \\ X &= Z, \text{ for odd } Z \\ &= Z+1, \text{ for even } Z, \end{aligned}$$

55

and further wherein said matrix column signal subset W_C is systolically coupled row-to-row within said matrix of processing means $N_{A,B}$, said coupled matrix column signal subset W_C having fewer signals when coupled from one of said rows of processing means $N_{A,B}$ to a subsequent row of

processing means $N_{A+1,B}$;

(c) coupling into said processing array a vector signal set V having vector signals V_J representing a vector parameter set selectively represented as a K -element vector having K parameters, wherein a vector column signal subset V_C of said vector signal set V is coupled into each processing means $N_{1,B}$ in a first one of said rows of processing means $N_{A,B}$, where

$$V_C = V_{Y,Z} = V_J$$

where:

$$J = Y - Z - P + \sum_{Z=1}^Z (P - Z + 2)$$

$$Z = 1, 2, 3, \dots, Q$$

$$Y = X, X+1, X+2, \dots, P$$

$$X = Z, \text{ for odd } Z$$

$$= Z+1, \text{ for even } Z; \text{ and}$$

(d) systolically processing said matrix W and vector V signal sets.

24. A processing method as recited in Claim 22 or 23, wherein said step of (b) coupling said matrix signal set W into said processing array further comprises coupling a matrix row signal subset W_R of said matrix signal set W into each processing means $N_{A,1}$ in a first one of said columns of processing means $N_{A,B}$, where

$$W_R = W_{A,B,Y,Z}$$

where:

$$J = Z - Y - Q + \sum_{Y=1}^Y (Q - Y + 2)$$

$$Y = 1, 2, 3, \dots, P$$

$$Z = X, X+1, X+2, \dots, Q$$

$$X = Y, \text{ for even } Y$$

$$= Y+1, \text{ for odd } Y,$$

and further wherein said matrix row signal subset W_R is systolically coupled column-to-column within said matrix of processing means $N_{A,B}$, said coupled matrix row signal subset W_R having fewer signals when coupled from one of said columns of processing means $N_{A,B}$ to a subsequent column of processing means $N_{A,B+1}$.

25. A processing method as recited in Claim 22 or 23, wherein said step of (b) coupling said matrix signal set W into said processing array further comprises coupling said matrix column signal subset W_C into each one of said processing means $N_{1,B}$ in said first row of processing means $N_{A,B}$ substantially simultaneously.

26. A processing method as recited in Claim 24 wherein said step of (b) coupling said matrix signal set W into said processing array further comprises coupling said matrix row signal subset W_R into each one of said processing means $N_{A,1}$ in said first column of processing means $N_{A,B}$ substantially simultaneously.

27. A processing method as recited in Claim 21 or 23, wherein said step (c) of coupling said vector signal set V into said processing array further comprises coupling a vector row signal subset V_R of said vector signal set V into each processing means $N_{A,1}$ in a first one of said columns of processing means $N_{A,B}$, where

$$V_R = V_{Y,Z} = V_J$$

where:

5

$$J = Z - Y - Q + \sum_{Y=1}^Y (Q - Y + 2)$$

10
 $Y = 1, 2, 3, \dots, P$
 $Z = X, X+1, X+2, \dots, Q$
 $X = Y, \text{ for even } Y$
 $= Y+1, \text{ for odd } Y.$

15
 28. A processing method as recited in Claim 21 or 23, wherein said step (c) of coupling said vector signal set V into said processing array further comprises coupling said vector column signal subset V_C into each one of said processing means $N_{1,B}$ in said first row of processing means $N_{A,B}$ substantially simultaneously.

20
 29. A processing method as recited in Claim 27, wherein said step (c) of coupling said vector signal set V into said processing array further comprises coupling said vector row signal subset V_R into each one of said processing means $N_{A,1}$ in said first column of processing means $N_{A,B}$ substantially simultaneously.
